What is Decision Tree Learning ?

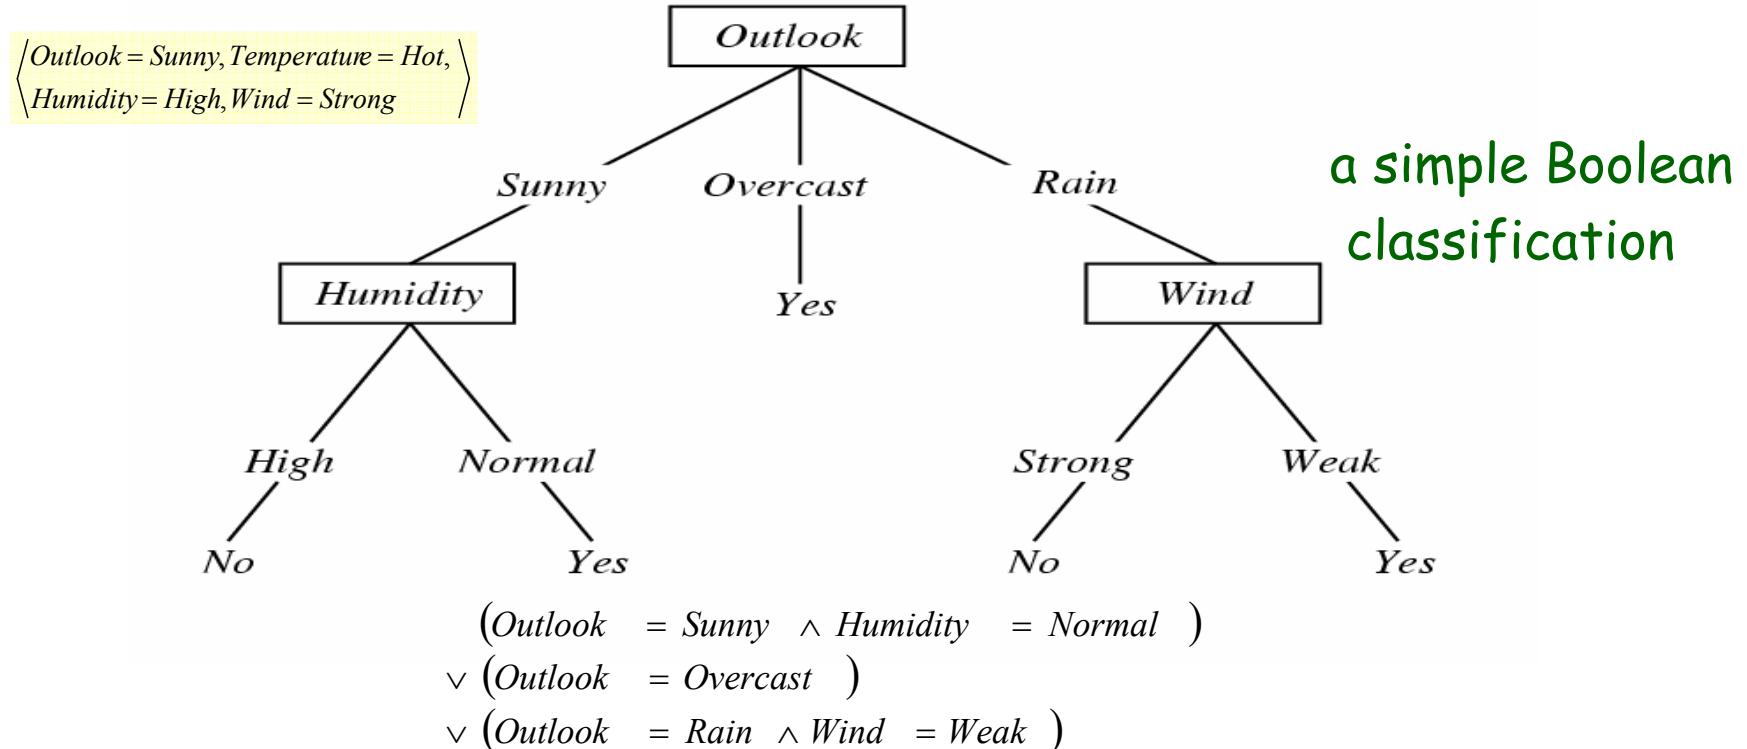

- Decision tree learning is a method for approximating **discrete-valued target functions** (classification results)
 - The learned function (classifier) is represented by a decision tree
 - Decision trees also can be re-represented as sets of **if-then rules** to improve human readability (or interpretability)
 - A **disjunction of conjunctions of constraints** (on attribute values)
- Decision tree learning is a kind of inductive learning
 - Belongs to the logical model (logic-based approach)
 - No assumption of distributions of examples
 - Classification is done by applying Boolean and comparative operators to the feature values
 - Output also in the form of logic expressions (statements)
 - A supervised learning method

What is a Decision Tree ? (1/2)

- Decision tree representation (for **Univariate Decision Trees**)
 - Each internal node tests an attribute
 - Some test to be carried out
 - Each branch corresponds to attribute value
 - Outcome of the test on a given attribute
 - Each leaf node assigns a classification label (or numeric value)
 - Indication of a class (or an output of the regression function)
- Decision trees are usually generated in a top-down manner
 - Greedy search methods are employed
 - No-backtracking

What is a Decision Tree ? (2/2)

- The decision tree (classification tree) represents a disjunction of conjunctions of constraints on the attribute values of instances
 - Each path from the tree root to a leaf corresponds to a conjunction of attribute tests (a classification rule)

Graphical Representation of a Classification Problem

Univariate Decision Tree

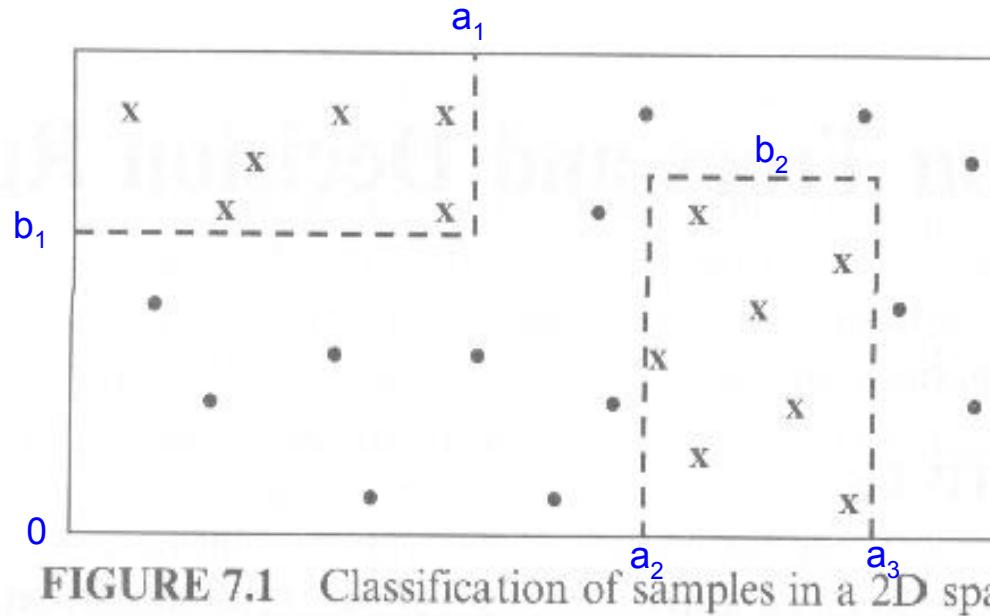

FIGURE 7.1 Classification of samples in a 2D space

- One or more hypercubes stand for a given class
 - OR-ed all the cubes to provide a complete classification for a class
 - Within a cube the conditions for each part are AND-ed
 - Size of the cube determines generality

When to Consider Decision Trees

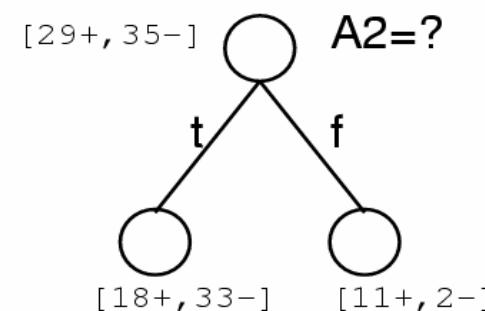

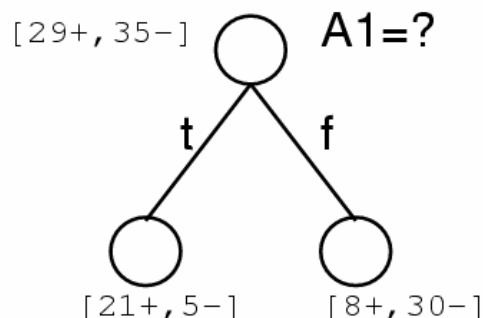

- Instances describable by attribute-value pairs
 - Symbolic or real-valued attributes
- Target function is discrete valued (or numeric)
- Disjunctive hypothesis may be required
- Possibly noisy training data
 - Errors in classifications or attribute values
- Training data containing missing attribute values
- Examples
 - Equipment or medical diagnosis
 - Credit risk analysis
 - Modeling calendar scheduling preferences

Key Requirements for Decision Trees

- Attribute-value description
 - A fixed collection of properties or attributes
 - Attribute description must not vary from one case to another
- Predefined classes
 - Categorical assignments must be established beforehand
 - Again, DTL is supervised learning
 - **A case can only belong to a particular class**
- Sufficient data
 - Enough number of patterns can be distinguished from chance coincidences

Top-Down Induction of Decision Trees

- Main loop (of the ID3 algorithm)
 - $A \leftarrow$ the “best” decision attribute for next node
 - Assign A as decision attribute for node
 - For each value of A create new descendant of node
 - Sort training examples to (new) leaf nodes
 - If training examples perfectly classified Then
STOP Else iterate over new leaf nodes
- Which attribute is best ?

ID3 Algorithm

$\text{ID3}(\text{Examples}, \text{Target_attribute}, \text{Attributes})$

Examples are the training examples. *Target_attribute* is the attribute whose value is to be predicted by the tree. *Attributes* is a list of other attributes that may be tested by the learned decision tree. Returns a decision tree that correctly classifies the given *Examples*.

- Create a *Root* node for the tree
- If all *Examples* are positive, Return the single-node tree *Root*, with label = +
- If all *Examples* are negative, Return the single-node tree *Root*, with label = -
- If *Attributes* is empty, Return the single-node tree *Root*, with label = most common value of *Target_attribute* in *Examples*
- Otherwise Begin
 - $A \leftarrow$ the attribute from *Attributes* that best* classifies *Examples*
 - The decision attribute for *Root* $\leftarrow A$
 - For each possible value, v_i , of *A*,
 - Add a new tree branch below *Root*, corresponding to the test $A = v_i$
 - Let Examples_{v_i} be the subset of *Examples* that have value v_i for *A*
 - If Examples_{v_i} is empty
 - Then below this new branch add a leaf node with label = most common value of *Target_attribute* in *Examples*
 - Else below this new branch add the subtree $\text{ID3}(\text{Examples}_{v_i}, \text{Target_attribute}, \text{Attributes} - \{A\})$
- End
- Return *Root*

Attribute Selection

- The only information available for the guidance of node splitting:
 - The distribution of classes for the samples in such a node and its associated children nodes
 - Purity or Impurity of a node
 - The distribution of values of the selected attribute for the samples in such a node and its associated children nodes
 - Number of distinct attribute values

Review: Entropy (1/3)

- Three interpretations for quantity of information
 1. The amount of **uncertainty** before seeing an event
 2. The amount of **surprise** when seeing an event
 3. The amount of **information** after seeing an event
- The definition of information:
$$I(x_i) = \log_2 \frac{1}{P(x_i)} = -\log_2 P(x_i)$$

define $0 \log_2 0 = 0$

 - $P(x_i)$ the probability of an event x_i
- Entropy: the average amount of information

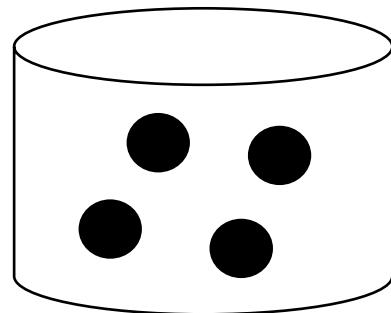

$$H(X) = E[I(X)]_X = E[-\log_2 P(x_i)]_X = \sum_{x_i} -P(x_i) \cdot \log_2 P(x_i)$$

- Have the maximum value when the probability where $X = \{x_1, x_2, \dots, x_i, \dots\}$ (mass) function is a uniform distribution

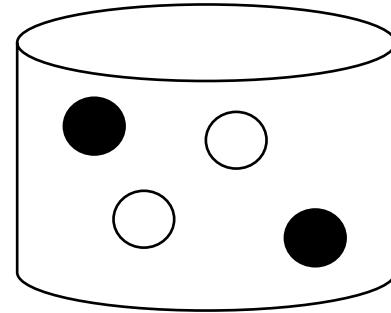

Review: Entropy (2/3)

- Entropy can characterize the (im)purity of an arbitrary collection S of examples
 - Entropy is 0 If all examples belong to the same class (or concept)

$$E(S) = -1 \cdot \log \frac{1}{1} = 0$$

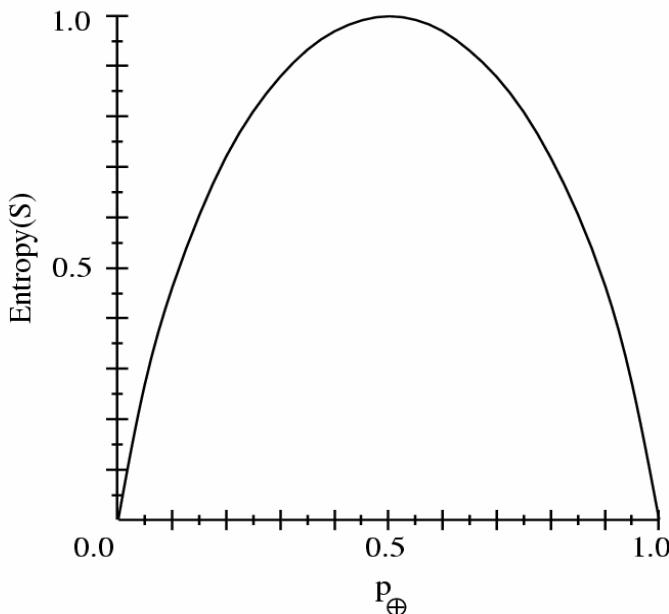

$$E(S) = -1 \cdot \log \frac{1}{1} = 0$$

$$E(S) = -\left(\frac{1}{2} \cdot \log \frac{1}{(1/2)} + \frac{1}{2} \cdot \log \frac{1}{(1/2)}\right) = \log 2 = 1$$

Review: Entropy (3/3)

- For Boolean classification (0 or 1)

$$\text{Entropy}(X) = -p_1 \log_2 p_1 - p_2 \log_2 p_2$$

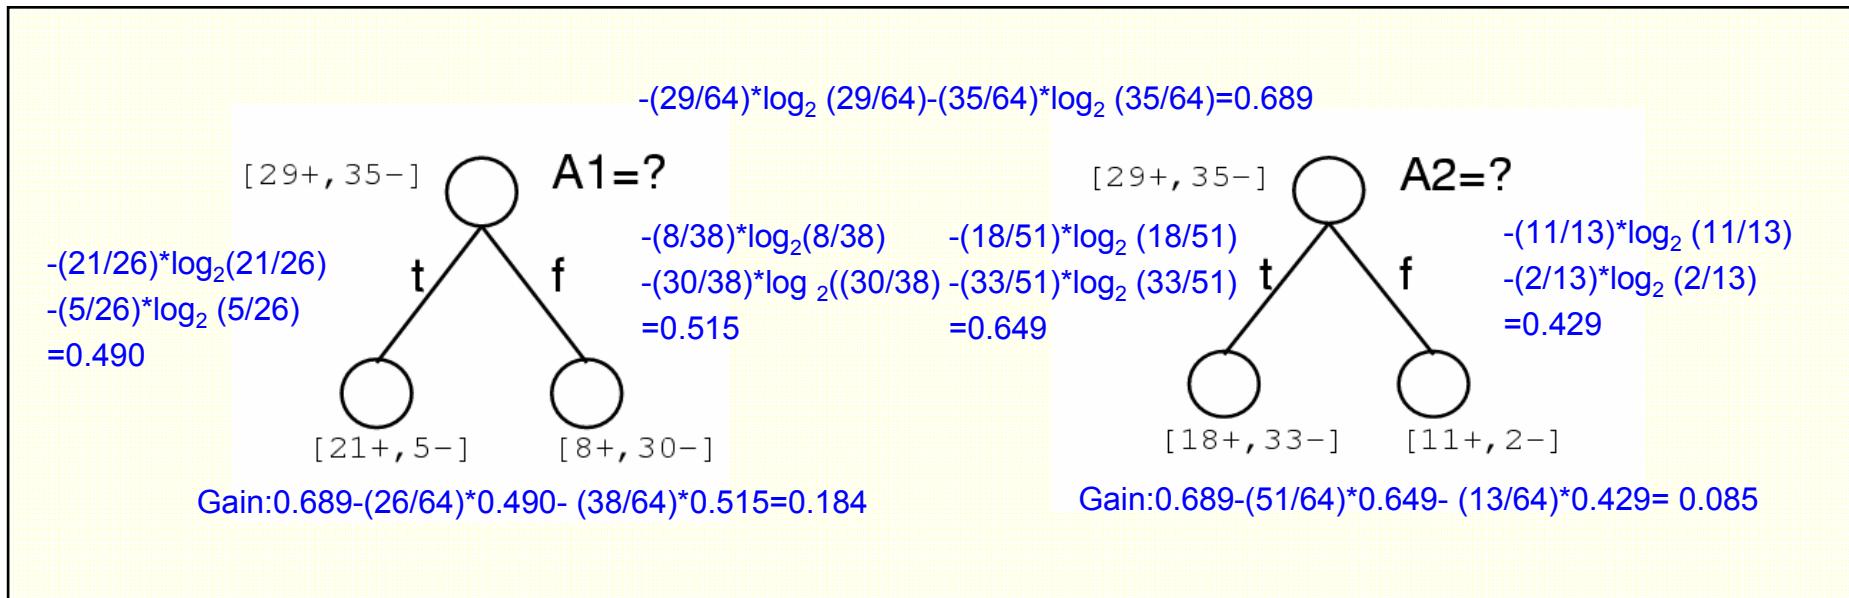

- Entropy can be expressed as **the minimum number of bits of information** needed to encode the classification of an arbitrary number of examples
 - If C classes are generated, the maximum of Entropy can be
- $$\text{Entropy}(X) = \log_2 C$$
-

Information Gain

- $\text{Gain}(S, A)$ =expected reduction in entropy due to sorting/partitioning on A

$$\text{Gain}(S, A) = \text{Entropy}(S) - \sum_{v \in \text{Values}(A)} \frac{|S_v|}{|S|} \text{Entropy}(S_v)$$

weighted sum of entropies over the subsets

An Illustrative Example (1/5)

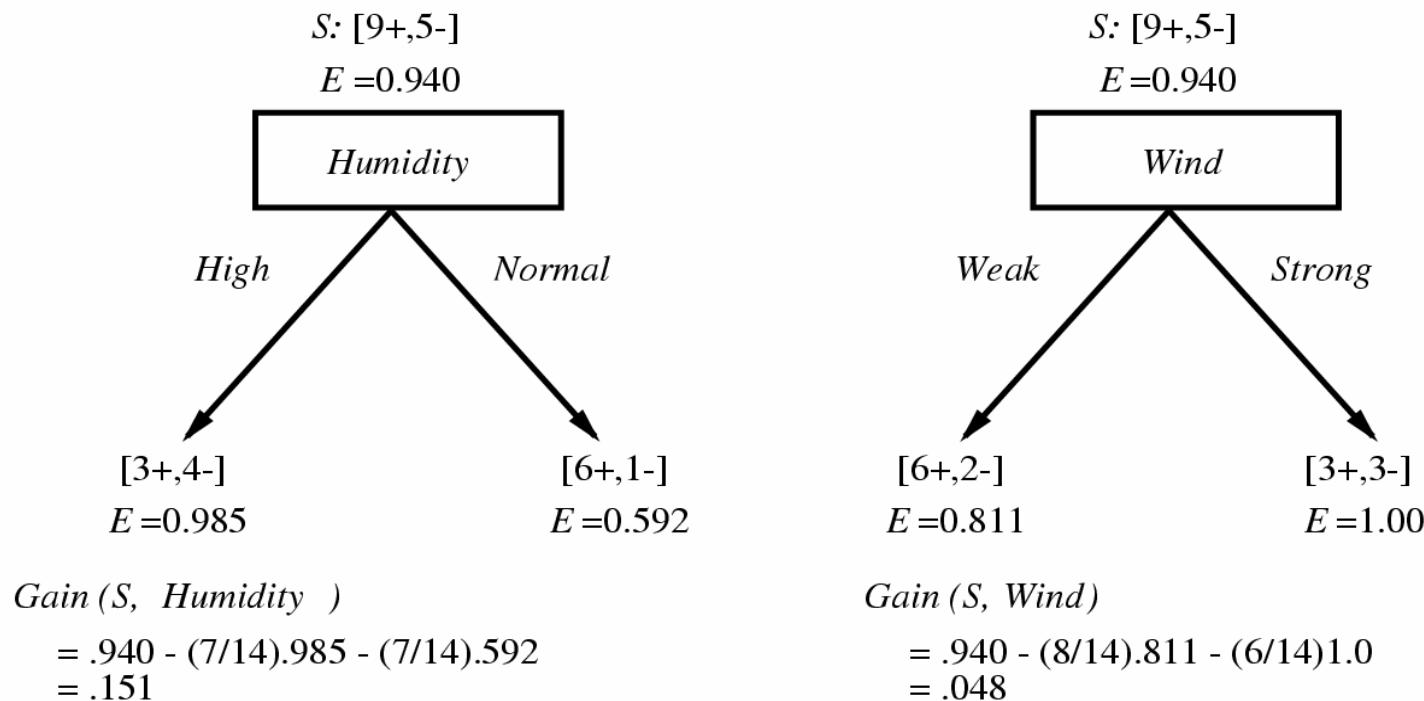

- Target Attribute: *PlayTennis*

Day	Outlook	Temperature	Humidity	Wind	PlayTennis
D1	Sunny	Hot	High	Weak	No
D2	Sunny	Hot	High	Strong	No
D3	Overcast	Hot	High	Weak	Yes
D4	Rain	Mild	High	Weak	Yes
D5	Rain	Cool	Normal	Weak	Yes
D6	Rain	Cool	Normal	Strong	No
D7	Overcast	Cool	Normal	Strong	Yes
D8	Sunny	Mild	High	Weak	No
D9	Sunny	Cool	Normal	Weak	Yes
D10	Rain	Mild	Normal	Weak	Yes
D11	Sunny	Mild	Normal	Strong	Yes
D12	Overcast	Mild	High	Strong	Yes
D13	Overcast	Hot	Normal	Weak	Yes
D14	Rain	Mild	High	Strong	No

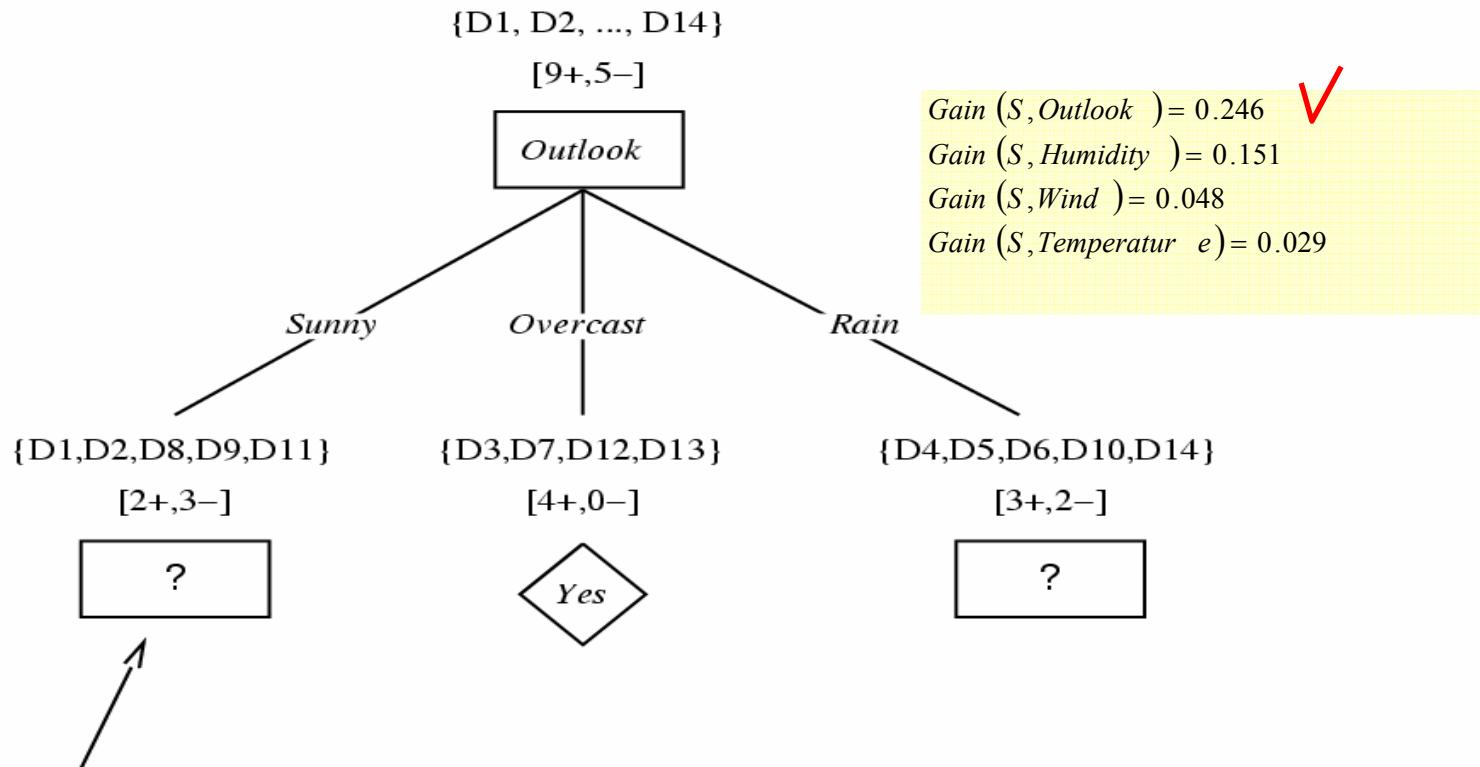

An Illustrative Example (2/5)

- Select the Next Features
 - For example, two different attributes are considered

Which attribute is the best classifier?

An Illustrative Example (3/5)

$$S_{\text{sunny}} = \{D1, D2, D8, D9, D11\}$$

$$\text{Gain}(S_{\text{sunny}}, \text{Humidity}) = .970 - (3/5) 0.0 - (2/5) 0.0 = .970$$

$$\text{Gain}(S_{\text{sunny}}, \text{Temperature}) = .970 - (2/5) 0.0 - (2/5) 1.0 - (1/5) 0.0 = .570$$

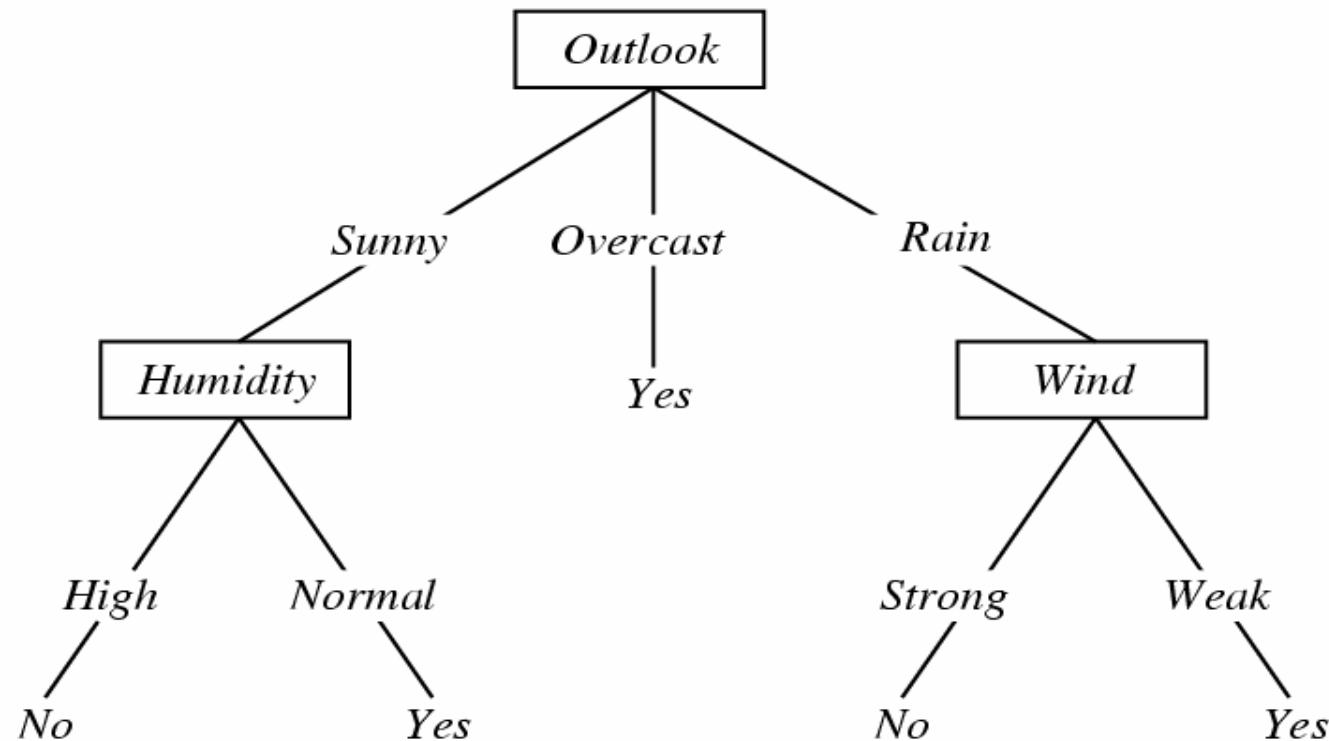

$$\text{Gain}(S_{\text{sunny}}, \text{Wind}) = .970 - (2/5) 1.0 - (3/5) .918 = .019$$

An Illustrative Example (4/5)

- The process of selecting a new attribute and partitioning the training examples is repeated for each nonterminal descendant node
 - Use the training samples associated with that node
 - Use the attributes that have not been used along the path through the tree
- The process terminates when either the following two conditions is met for each new leaf node
 - Every attribute has already been included along the path through the tree
 - The training examples associated with this leaf node have the same target attribute value (entropy is zero)

An Illustrative Example (5/5)

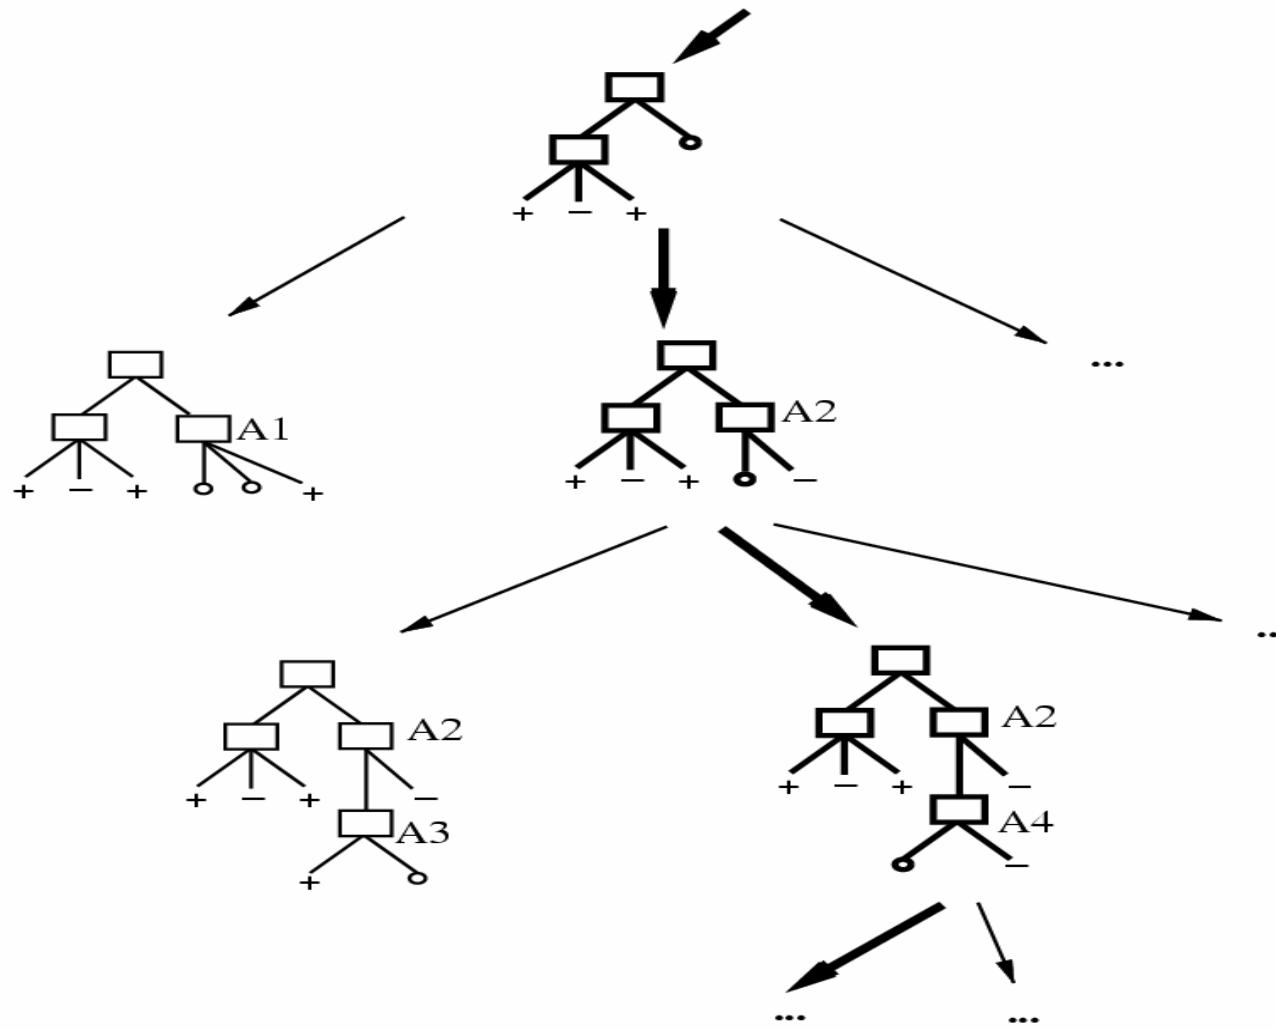

- The final decision tree

Hypothesis Space Search by ID3 (1/2)

- Hypothesis space is complete
 - Target function surely in there
- Outputs a single hypothesis (which one?)
 - Can not explicitly represent all consistent hypotheses
- No backtracking
 - Output a locally optimal solution (not globally optimal)
- Statistically based search choices
 - Robust to noisy data
 - Use the statistical properties of all samples, do not make decisions incrementally based on individual training examples
- Inductive bias
 - Implicitly select in favor of short trees over longer ones

Hypothesis Space Search by ID3 (2/2)

Inductive Bias in ID3

- Inductive bias
 - The set of assumptions that, together with the training data, deductively justify the classifications assigned by the learner to further instances
- Inductive bias exhibited by ID3
 - As mentioned, select in favor of short trees over longer ones
 - Select trees that place the attributes with highest information gain closest to the root
- Again, ID3 can be characterized as follows
 - A greedy search using the information gain heuristic
 - Does not always find the shortest consistent tree
 - No backtracking

Restriction Biases and Preference Biases

- Version Space Candidate-Elimination Algorithm concept learning
 - An incomplete hypothesis space (only a subset of hypotheses is expressed) introduces **a hard restriction bias** (or a language bias)
 - A complete search strategy introduces no bias
- ID3
 - A complete hypothesis space introduces no bias
 - An incomplete search strategy introduces **a preference bias** (or a **search bias**)
- Learning the numerical evaluation for Checkers
 - A linear combination of a fixed set of board features
→ **a restriction bias**
 - LMS algorithm → **a preference bias**
- A preference bias is more desirable than a restriction bias

Occam's Razor

- Why prefer short hypotheses ?
- Argument in favor
 - Fewer short hypotheses than long hypotheses
 - A short hypothesis that fits data unlikely to be coincidence
 - A long hypothesis that fits data might be coincidence
 - Overfit the training examples

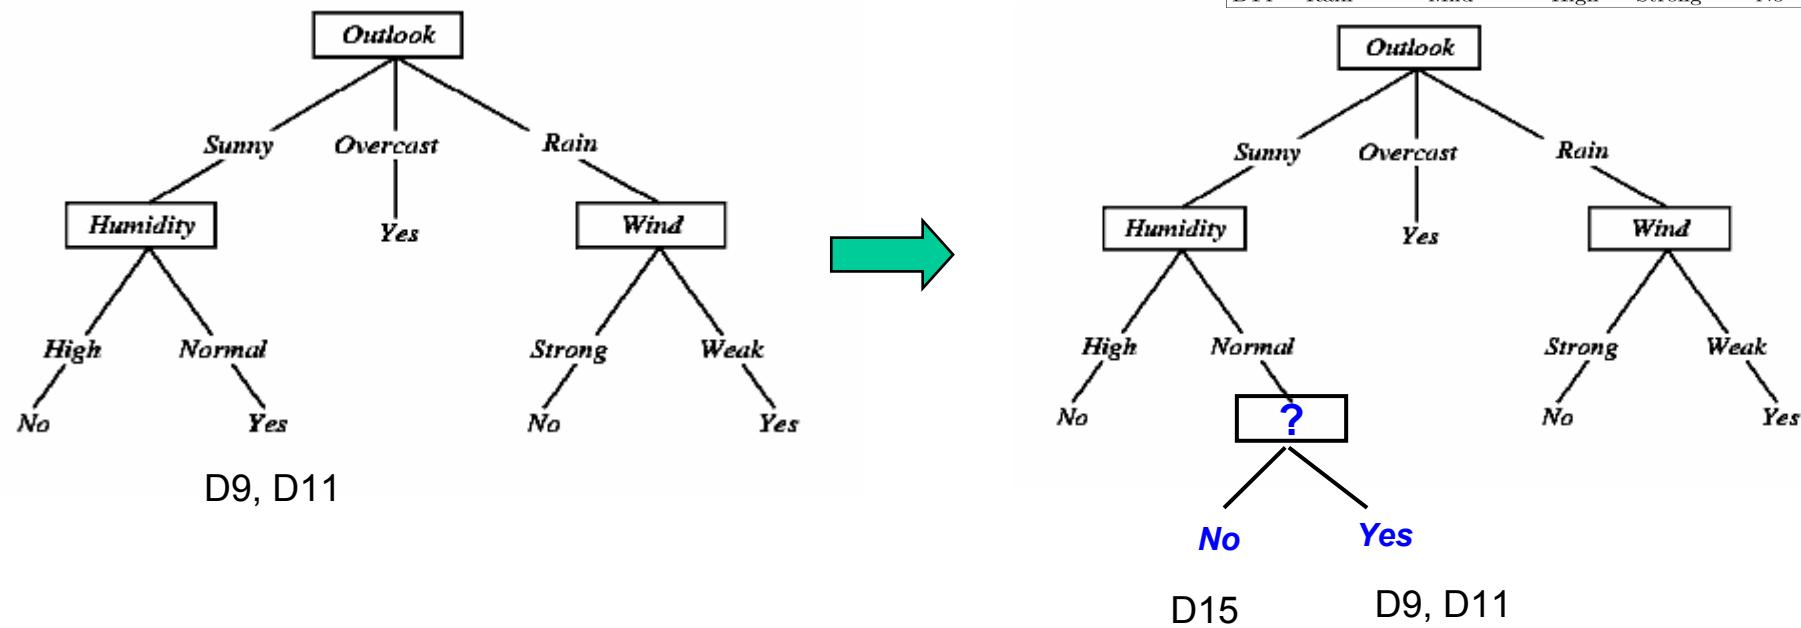

Issues in Decision Tree Learning

- Avoiding Overfitting the Data
- Incorporating Continuous-Valued Attributes
- Alternative Measures for Selecting Attributes
 - E.g., for two-class problems: using Gini Index , $2p(1-p)$, instead of Entropy
- Handling Training Examples with Missing Attribute Values
- Handling Attributes with Differing Costs

Overfitting in Decision Trees

- Consider adding a noisy training example, D15
 - Sunny, Hot, Normal, Strong, PlayTennis=No*
- What effect on earlier tree ?

Day	Outlook	Temperature	Humidity	Wind	PlayTennis
D1	Sunny	Hot	High	Weak	No
D2	Sunny	Hot	High	Strong	No
D3	Overcast	Hot	High	Weak	Yes
D4	Rain	Mild	High	Weak	Yes
D5	Rain	Cool	Normal	Weak	Yes
D6	Rain	Cool	Normal	Strong	No
D7	Overcast	Cool	Normal	Strong	Yes
D8	Sunny	Mild	High	Weak	No
D9	Sunny	Cool	Normal	Weak	Yes
D10	Rain	Mild	Normal	Weak	Yes
D11	Sunny	Mild	Normal	Strong	Yes
D12	Overcast	Mild	High	Strong	Yes
D13	Overcast	Hot	Normal	Weak	Yes
D14	Rain	Mild	High	Strong	No

- The random noise introduced in the training examples can lead to overfitting

Overfitting

- Consider error of hypothesis h over
 - Training data: $\text{error}_{\text{train}}(h)$
 - Entire distribution D of data $\text{error}_D(h)$

Hypothesis $h \in H$ overfits training data if there is an alternative hypothesis $h' \in H$ such that

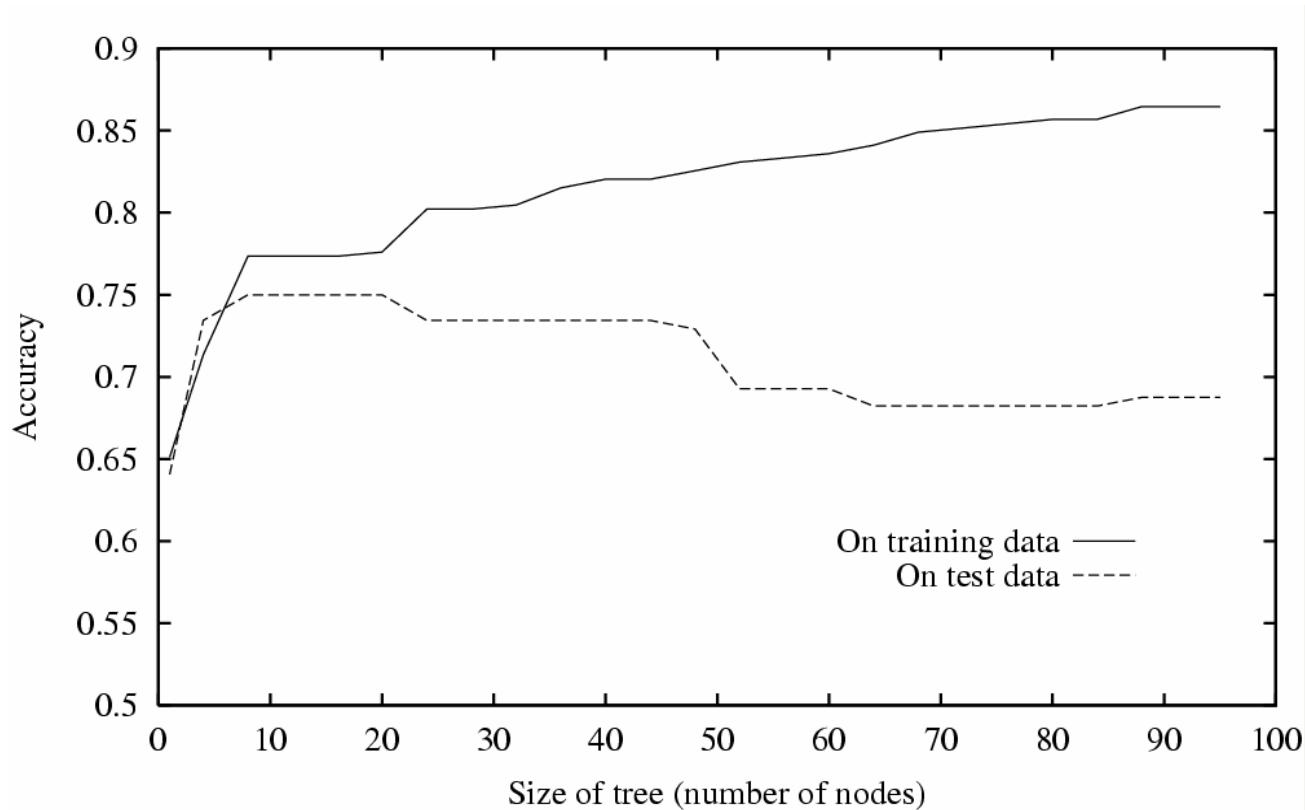

$$\text{error}_{\text{train}}(h) < \text{error}_{\text{train}}(h')$$

and

$$\text{error}_D(h) > \text{error}_D(h')$$

Overfitting in Decision Tree Learning

- Example: Prediction of Diabetes

- Accuracy measured over training example increases monotonically
- Accuracy measured over independent test example first increases and then decreases

Pruning Decision Trees

- Remove parts of the decision tree (subtrees) that do not contribute to the classification accuracy of unseen testing samples (mainly because of overfitting)
 - Produce a less complex and more comprehensible tree
- Two ways
 - Prepruning: Stop growing when data split not statistically significant (earlier stop before perfect classification of training data)
 - Hard to estimate precisely
 - Postpruning: Grow full tree, then post-prune the tree
 - Much more promising

Avoiding Overfitting

- How to select the best tree (the correct final tree size)?
 - Measure performance over separate validation data set (training- and validation-set approach)
 - Measure performance over training data
 - Statistical tests, e.g., if there are no significant different in classification accuracy before and after splitting, then represent a current node as a leaf (called **prepruning**)
 - MDL (Minimum Description Length) minimize ?
 - $\text{size}(\text{tree}) + \text{size}(\text{misclassifications}(\text{tree}))$

Reduced-Error Pruning

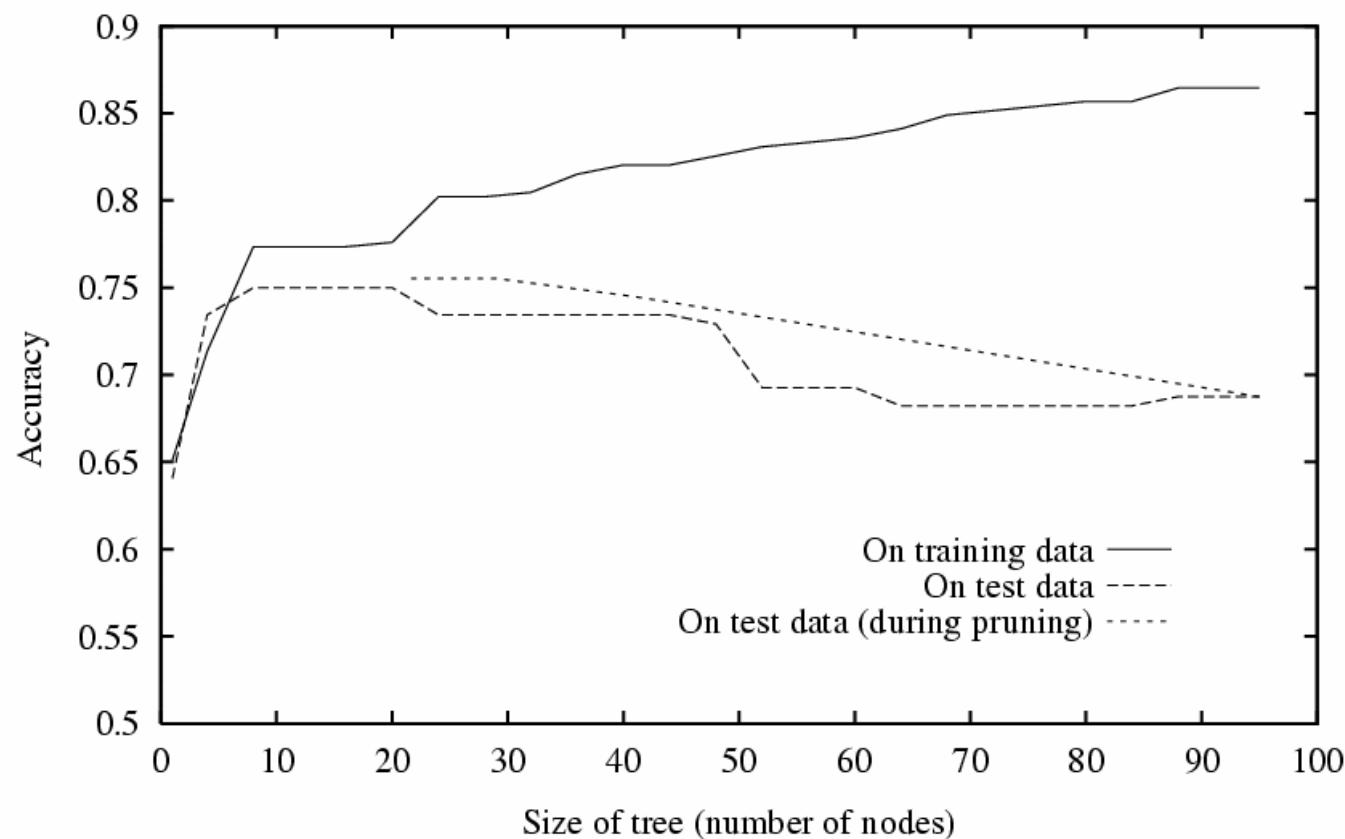

- Split data into *training* (2/3) and *validation* (1/3) set, and do until further pruning is harmful:
 1. Evaluate impact on validation set of pruning each possible node (plus those below it)
 2. Greedily remove the one that most improves validation set accuracy
 - Prune leaf nodes added due to coincidental regularities in the training set

Produces smallest version of most accurate subtree

What if data is limited ?

Effect of Reduced-Error Pruning

- Split data into three subsets
 - Training, Validation, Test

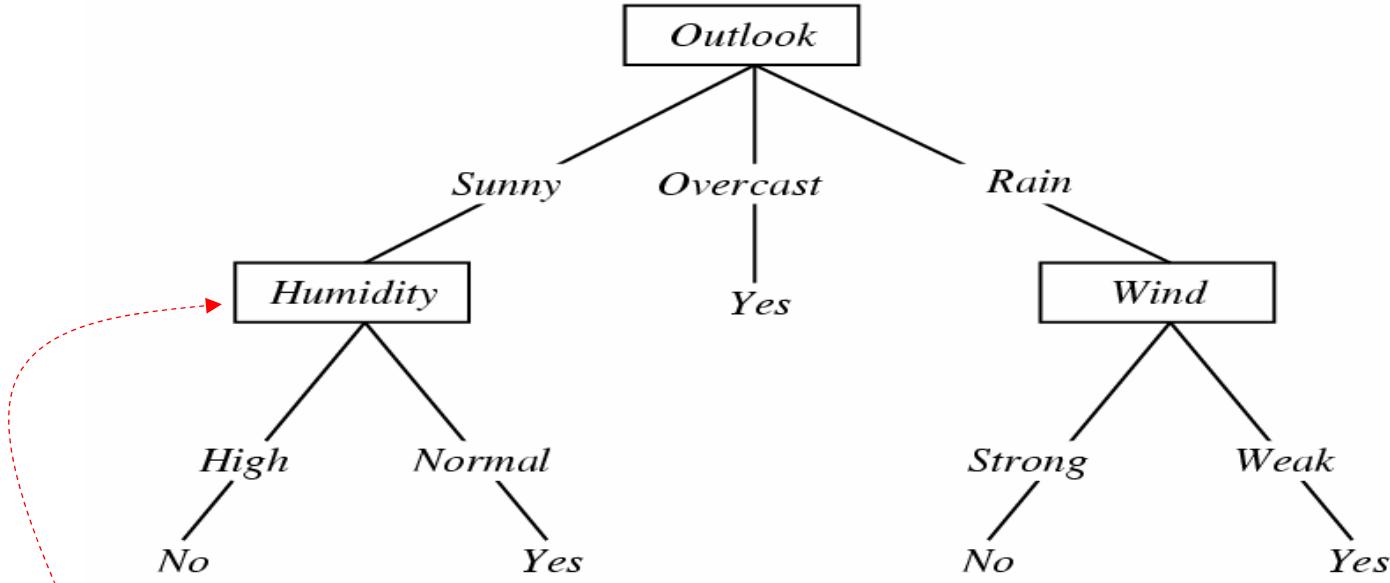

Rule Post-Pruning

1. Convert tree to equivalent set of rules
2. Prune (generalize) each rule independently of others
3. Sort final rules into desired sequence for use

Perhaps most frequently used method (e.g., C4.5)

IF $(Outlook = Sunny) \wedge (Humidity = High)$
THEN $PlayTennis = No$

Converting A Tree to Rules

IF $(Outlook = \text{Sunny}) \wedge (\text{Humidity} = \text{High})$
THEN $\text{PlayTennis} = \text{No}$

IF $(Outlook = \text{Sunny}) \wedge (\text{Humidity} = \text{Normal})$
THEN $\text{PlayTennis} = \text{Yes}$

Incorporating Continuous-Valued Attributes

- Create a discrete attribute to test continuous values
 - $\text{Temperature} = 82.5$
 - $(\text{Temperature} > 72.3) = t, f$
- Split into two intervals

<i>Temperature:</i>	40	48	60	72	80	90
<i>PlayTennis:</i>	No	No	Yes	Yes	Yes	No
			A			A
		$(48+60)/2$			$(80+90)/2$	
		=54			=85	

- Candidate thresholds evaluated by computing the information gain associated with each
- Split into multiple intervals

Attributes with Many Values

- Problem:
 - If attribute has many values, *Gain* will select it (E.g., imagine using Date= Jun_3_1996 as attribute)
 - Training set separated into very small subsets
 - Have highest information gain
- One approach: use *GainRatio* instead

$$GainRatio(S, A) = \frac{Gain(S, A)}{SplitInformation(S, A)}$$

Day	Outlook	Temperature	Humidity	Wind	PlayTennis
D1	Sunny	Hot	High	Weak	No
D2	Sunny	Hot	High	Strong	No
D3	Overcast	Hot	High	Weak	Yes
D4	Rain	Mild	High	Weak	Yes
D5	Rain	Cool	Normal	Weak	Yes
D6	Rain	Cool	Normal	Strong	No
D7	Overcast	Cool	Normal	Strong	Yes
D8	Sunny	Mild	High	Weak	No
D9	Sunny	Cool	Normal	Weak	Yes
D10	Rain	Mild	Normal	Weak	Yes
D11	Sunny	Mild	Normal	Strong	Yes
D12	Overcast	Mild	High	Strong	Yes
D13	Overcast	Hot	Normal	Weak	Yes
D14	Rain	Mild	High	Strong	No

$$SplitInformation(S, A) = -\sum_{i=1}^c \frac{|S_i|}{|S|} \log_2 \frac{|S_i|}{|S|}$$

Entropy of S with respect to the values of attribute A

- Where S_i is subset of S for which A has value v_i
- *SplitInformation* discourages the selection of attributes with many uniformly distributed values

Attributes with Costs

- Instance attributes may have associated costs
- How to learn a consistent tree with low expected cost ?
- One approach: replace gain by
 - Tan and Schlimmer (1990)

$$\frac{Gain^2(S, A)}{Cost(A)}$$

- Nunez (1988)

introduce a cost term into the attribute selection measure
- Low-cost attributes preferred
- No guarantee to find optimal DTL

$$\frac{2^{Gain(S, A)} - 1}{(Cost(A) + 1)^w}$$

where $w \in [0, 1]$ determines importance of cost

Unknown Attribute Values (1/4)

- What if some examples missing values of A ?
 - In a data set, some attribute values for some examples can be missing, for example, because that
 - The value is not relevant to a particular examples
 - The value is not recorded when the data was collected
 - An error was made when entering data into a database
- Two choices to solve this problem
 - Discard all examples in a database with missing data
 - What if large amounts of missing values exists ?
 - Define a new algorithm or modify an existing algorithm that will work with missing data

Unknown Attribute Values (2/4)

- One approach: Use training example anyway sort through tree
 - Fill a missing value with most probable value
 - If node n tests A , assign most common value of A among other examples sorted to node n
 - Assign most common value of A among other examples sorted to node n with same target value
 - Fill a missing value based on the probability distribution of all values for the given attribute
 - Assign probability p_i to each possible value v_i of A at node n
 - Assign fraction p_i of example to each descendant in tree
- Also, the unseen test data with missing attribute values can be classified in similar fashion

Unknown Attribute Values (3/4)

- Example

TABLE 7.2. A simple flat database of examples with one missing value

Database T:

Attribute1	Attribute2	Attribute3	Class
A	70	True	CLASS1
A	90	True	CLASS2
A	85	False	CLASS2
A	95	False	CLASS2
A	70	False	CLASS1
?	90	True	CLASS1
B	78	False	CLASS1
B	65	True	CLASS1
B	75	False	CLASS1
C	80	True	CLASS2
C	70	True	CLASS2
C	80	False	CLASS1
C	80	False	CLASS1
C	96	False	CLASS1

$$Gain(S, A) = F \left(Entropy(S) - \sum_{v \in Values(A)} \frac{|S_v|}{|S|} Entropy(S_v) \right)$$

F : no. of examples with a known value for a given attribute divided by total no. of examples

$Entropy(S)$

$$= -8/13 \log_2(8/13) - 5/13 \log_2(5/13) \\ = 0.961$$

$$\sum_{v \in Values(A)} \frac{|S_v|}{|S|} Entropy(S_v)$$

$$= 5/13(-2/5 \log_2(2/5) - 3/5 \log_2(3/5)) \\ + 3/13(-3/3 \log_2(3/3) - 0/3 \log_2(0/0)) \\ + 5/13(-3/5 \log_2(3/5) - 2/5 \log_2(2/5)) \\ = 0.747$$

$$Gain(S, A) = 13/14(0.961 - 0.747) = 0.199$$

$SplitInformation(S, A)$

$$= -(5/14 \log 5/14 + 3/14 \log 3/14) \\ + 5/14 \log 5/14 + 1/14 \log 1/14 \\ = 1.876$$

$$GainRatio(S, A) = \frac{0.199}{1.876}$$

Treat the example with missing value as a specific group

Unknown Attribute Values (4/4)

- Example (cont.)
 - If node n tests A , assign most common value of A among other training examples sorted to node n

$T_1: (Attribute1 = A)$				$T_2: (Attribute1 = B)$				$T_3: (Attribute1 = C)$			
Att.2	Att.3	Class	w	Att.2	Att.3	Class	w	Att.2	Att.3	Class	w
70	True	CLASS1	1	90	True	CLASS1	3/13	80	True	CLASS2	1
90	True	CLASS2	1	78	False	CLASS1	1	70	True	CLASS2	1
85	False	CLASS2	1	65	True	CLASS1	1	80	False	CLASS1	1
95	False	CLASS2	1	75	False	CLASS1	1	80	False	CLASS1	1
70	False	CLASS1	1					96	False	CLASS1	1
90	True	CLASS1	5/13					90	True	CLASS1	5/13

FIGURE 7.7 Results of test x_1 are subsets T_i (initial set T is with missing value).

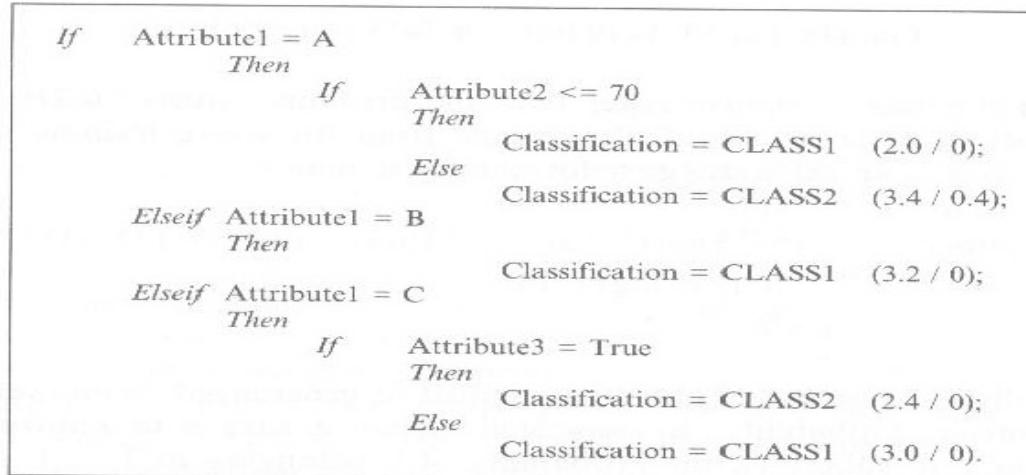

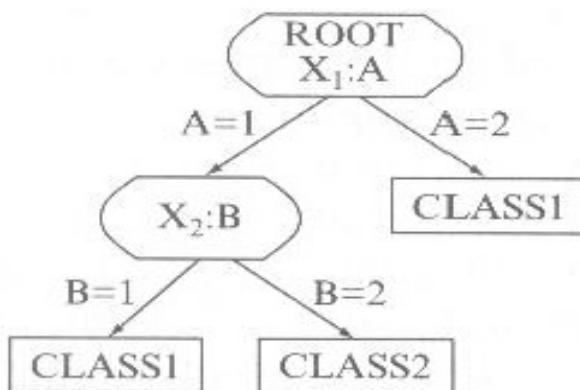

FIGURE 7.8 Decision tree for the database T with missing values

Generating Decision Rules

- In a decision tree, a path to each leaf can be transformed into an IF-THEN production rule
 - The IF part consists of all tests on a path
 - The THEN part is a final classification
- The IF parts of the rules are mutual exclusive and exhaustive

a) Decision tree

Transformation
=====⇒
Paths into Rules

If A=1 and B=1 Then CLASS1
If A=1 and B=2 Then CLASS2
If A=2 Then CLASS1

b) Decision rules

FIGURE 7.10 Transformation of a decision tree into decision rules

Reducing Complexity of Decision Trees

- One possible approach is to reduce the number of attribute values (i.e. branch number of a node)
 - A large number of values causes a large space of data
- Group the attributes values

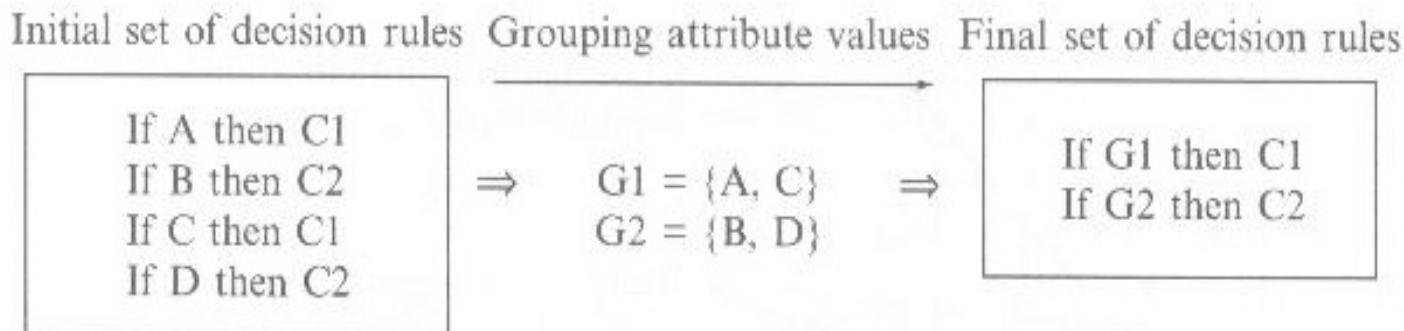

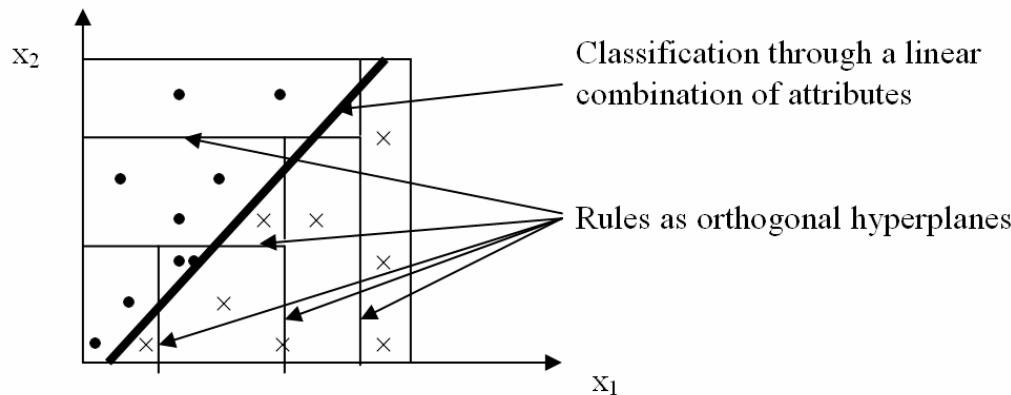

FIGURE 7.11 Grouping attribute values can reduce decision-rules set

Pro and Con for DTL

- Pro
 - Relatively simple, readable, and fast
 - Do not depend on underlying assumptions about distribution of attribute values or independence of attributes
- Con
 - Complex classifications require a large number of training sample to obtain a successful classification
 - Orthogonality of attributes is assumed during classification

What if a class is defined through a linear (weighted) combination of attributes

Summary

- DTL provides a practical method for concept learning and for learning other discrete-valued function
- ID3 searches a complete hypothesis space but employs an incomplete search strategy
- Overfitting the training data is an important issue in DTL
- A large variety of extensions to the basic ID3 algorithm has been developed
