# Taxonomy of Classic IR Models

# Statistical Language Models (1/2)

- A probabilistic mechanism for “generating” a piece of text
  - Defines a distribution over all possible word sequences

$$W = w_1 w_2 \dots w_N$$

$$P(W) = ?$$

- What is LM Used for ?
  - Speech recognition
  - Spelling correction
  - Handwriting recognition
  - Optical character recognition
  - Machine translation
  - Document classification and routing
  - Information retrieval ...

# Statistical Language Models (2/2)

- (Statistical) language models (LM) have been widely used for speech recognition and language (machine) translation for more than twenty years
- However, their use for use for information retrieval started only in 1998 [Ponte and Croft, SIGIR 1998]

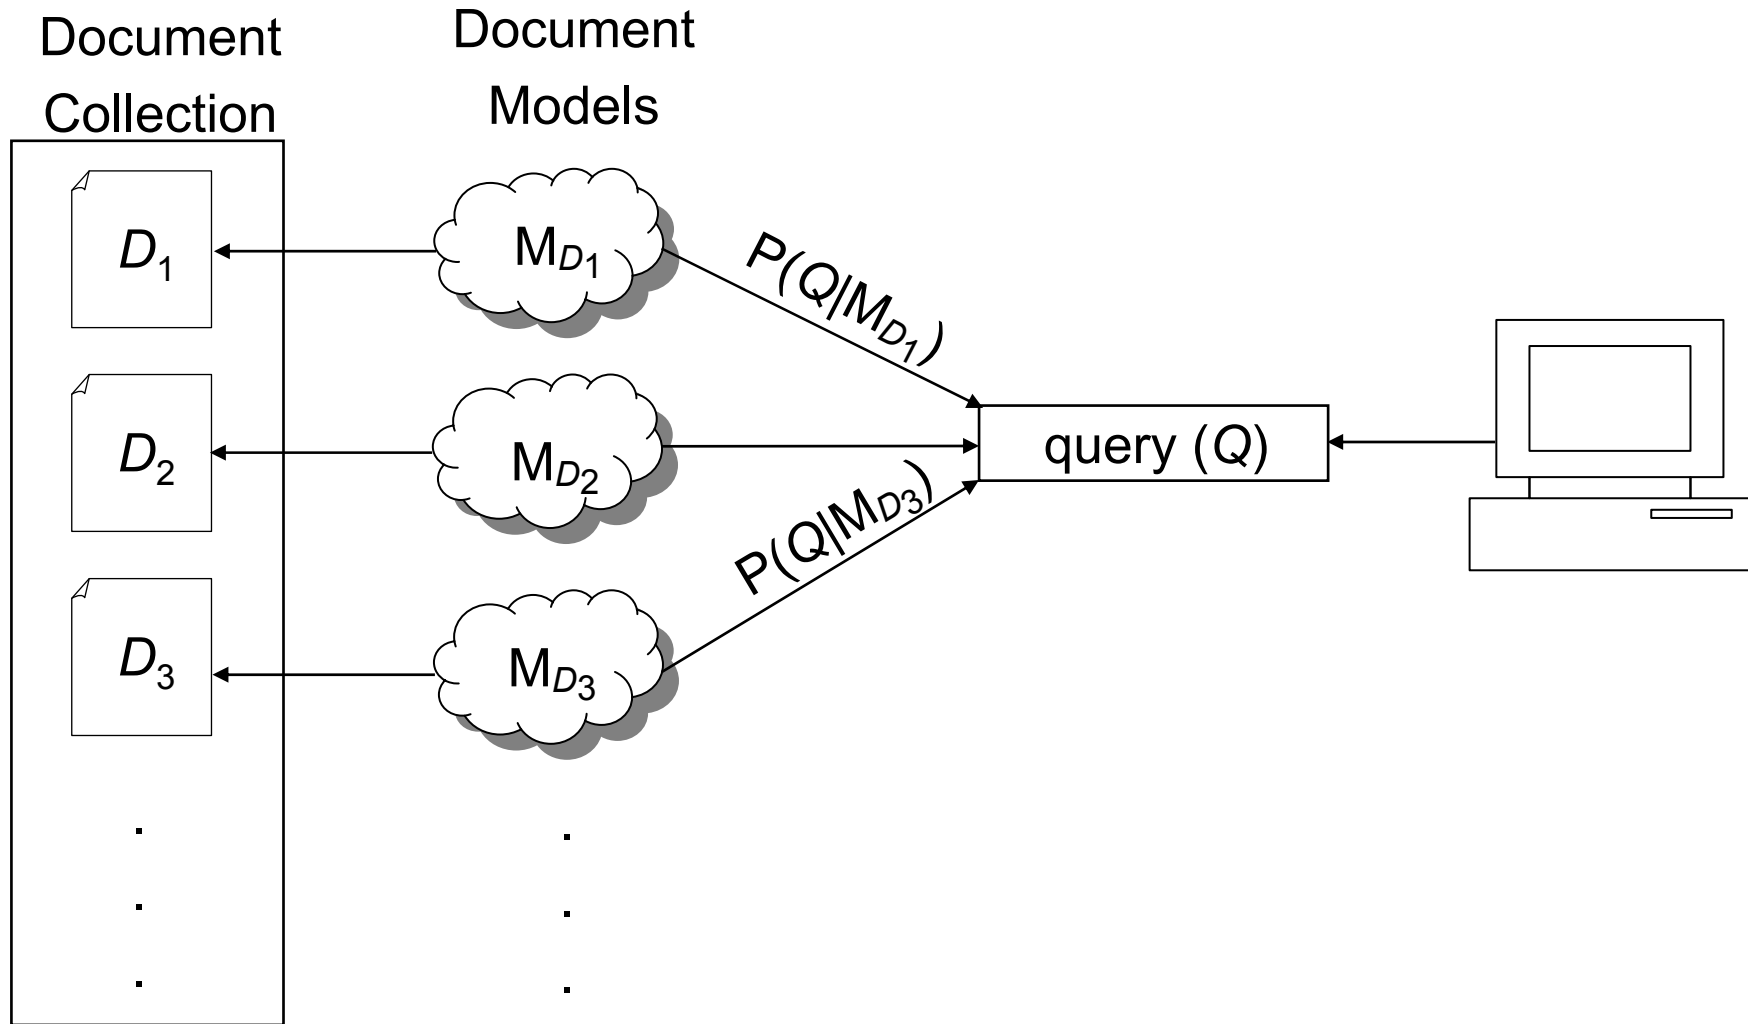

# Query Likelihood Language Models

- Documents are ranked based on Bayes (decision) rule

$$P(D|Q) = \frac{P(Q|D)P(D)}{P(Q)}$$

- $P(Q)$  is the same for all documents, and can be ignored
- $P(D)$  might have to do with authority, length, genre, etc.
  - There is no general way to estimate it
  - Can be treated as uniform across all documents
- Documents can therefore be ranked based on
$$P(Q|D) \quad (\text{or denoted as } P(Q|M_D))$$
  - The user has a prototype (ideal) document in mind, and generates a query based on words that appear in this document
  - A document  $D$  is treated as a model  $M_D$  to predict (generate) the query

# Schematic Depiction

# *n*-grams

- Multiplication (Chain) rule

$$P(w_1 w_2 \dots w_N) = P(w_1) P(w_2 | w_1) P(w_3 | w_1 w_2) \dots P(w_N | w_1 w_2 \dots w_{N-1})$$

- Decompose the probability of a sequence of events into the probability of each successive events conditioned on earlier events

- *n*-gram assumption

- Unigram

$$P(w_1 w_2 \dots w_N) = P(w_1) P(w_2) P(w_3) \dots P(w_N)$$

- Each word occurs independently of the other words
- The so-called “bag-of-words” model

- Bigram

$$P(w_1 w_2 \dots w_N) = P(w_1) P(w_2 | w_1) P(w_3 | w_2) \dots P(w_N | w_{N-1})$$

- Most language-modeling work in IR has used unigram language models

- IR does not directly depend on the structure of sentences

# Unigram Model (1/4)

- The likelihood of a query  $Q = w_1 w_2 \dots w_N$  given a document  $D$

$$\begin{aligned} P(Q|M_D) &= P(w_1|M_D)P(w_2|M_D)\cdots P(w_N|M_D) \\ &= \prod_{i=1}^N P(w_i|M_D) \end{aligned}$$

- Words are conditionally independent of each other given the document
- How to estimate the probability of a (query) word given the document  $P(w|M_D)$  ?
- Assume that words follow a **multinomial distribution** given the document

$$P(C(w_1), \dots, C(w_V) | M_D) = \frac{(\sum_{j=1}^V C(w_j))!}{\prod_{i=1}^V (C(w_i)!) } \prod_{i=1}^V \lambda_{w_i}^{C(w_i)}$$

permutation is considered here

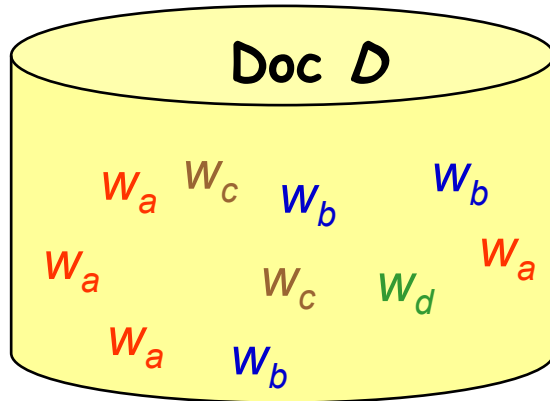

where  $C(w_i)$ : the number of times a word occurs

$$\lambda_{w_i} = P(w_i|M_D), \quad \sum_{i=1}^V \lambda_{w_i} = 1$$

# Unigram Model (2/4)

- Use each document itself a sample for estimating its corresponding unigram (multinomial) model
  - If Maximum Likelihood Estimation (MLE) is adopted

$$P(w_b | M_D) = 0.3$$

$$P(w_c | M_D) = 0.2$$

$$P(w_d | M_D) = 0.1$$

$$P(w_e | M_D) = 0.0$$

$$P(w_f | M_D) = 0.0$$

$$\hat{P}(w_i | M_D) = \frac{C(w_i, D)}{|D|}$$

where

$C(w_i, D)$ : number of times  $w_i$  occurs in  $D$

$|D|$ : length of  $D$ ,  $\sum_i C(w_i, D) = |D|$

## The zero-probability problem

If  $w_e$  and  $w_f$  do not occur in  $D$

then  $P(w_e | M_D) = P(w_f | M_D) = 0$

This will cause a problem in predicting the query likelihood (See the equation for the query likelihood in the preceding slide)

# Unigram Model (3/4)

- Smooth the document-specific unigram model with a collection model (a mixture of two multinomials)

$$P(Q|M_D) = \prod_{i=1}^N [\lambda \cdot P(w_i|M_D) + (1 - \lambda) \cdot P(w_i|M_C)]$$

- The role of the collection unigram model  $P(w_i|M_C)$ 
  - Help to solve zero-probability problem
  - Help to differentiate the contributions of different missing terms in a document (global information like IDF ?)
- The collection unigram model can be estimated in a similar way as what we do for the document-specific unigram model

# Unigram Model (4/4)

- An evaluation on the Topic Detection and Tracking (TDT) corpora
  - Language Model

mAP		Unigram	Unigram+Bigram
TDT2	TQ/TD	<b>0.6327</b>	0.5427
	TQ/SD	0.5658	0.4803
TDT3	TQ/TD	<b>0.6569</b>	0.6141
	TQ/SD	0.6308	0.5808

- Vector Space Model

mAP		Unigram	Unigram+Bigram
TDT2	TQ/TD	0.5548	<b>0.5623</b>
	TQ/SD	0.5122	<b>0.5225</b>
TDT3	TQ/TD	0.6505	<b>0.6531</b>
	TQ/SD	0.6216	0.6233

$$P_{Unigram}(Q|M_D) = \prod_{i=1}^N [\lambda \cdot P(w_i|M_D) + (1-\lambda) \cdot P(w_i|M_C)]$$

$$P_{Unigram+Bigram}(Q|M_D) = \prod_{i=1}^N [\lambda_1 \cdot P(w_i|M_D) + \lambda_2 \cdot P(w_i|M_C) + \lambda_3 \cdot P(w_i|w_{i-1},M_D) + (1-\lambda_1-\lambda_2-\lambda_3) \cdot P(w_i|w_{i-1},M_C)]$$

# Maximum Mutual Information

- Documents can be ranked based their mutual information with the query

$$\begin{aligned} MI(Q, D) &= \log \frac{P(Q, D)}{P(Q)P(D)} \\ &= \log P(Q|D) - \underbrace{\log P(Q)} \end{aligned}$$

being the same for all documents,  
and hence can be ignored

- Document ranking by mutual information (MI) is equivalent that by likelihood

$$\arg \max_D MI(Q, D) = \arg \max_D P(Q|D)$$

# Probabilistic Latent Semantic Analysis (PLSA)

Thomas Hofmann 1999

- Also called The Aspect Model, Probabilistic Latent Semantic Indexing (PLSI)
  - Graphical Model Representation (a kind of Bayesian Networks)

Language model

$$\begin{aligned} \text{sim}(Q, D) &= P(D|Q) = \frac{P(Q|D)P(D)}{P(Q)} \\ &\propto P(Q|D)P(D) \\ &\approx P(Q|D) \\ &= \prod_{w \in Q} [\lambda \cdot P(w|M_D) + (1-\lambda) \cdot P(w|M_C)]^{C(w,Q)} \end{aligned}$$

PLSA

$$\begin{aligned} \text{sim}(Q, D) &= P(Q|D) = \prod_{w \in Q} P(w|D)^{C(w,Q)} \\ &= \prod_{w \in Q} \left[ \sum_{k=1}^K P(w, T_k | D) \right]^{C(w,Q)} \\ &= \prod_{w \in Q} \left[ \sum_{k=1}^K P(w|T_k) P(T_k|D) \right]^{C(w,Q)} \end{aligned}$$

The latent variables  
=>The unobservable class variables  $T_k$   
(topics or domains)

Reference:

# PLSA: Formulation

- Definition

- $P(D)$  : the prob. when selecting a doc  $D$

- $P(T_k|D)$ : the prob. when pick a latent class  $T_k$  for the doc  $D$

- $P(w|T_k)$ : the prob. when generating a word  $w$  from the class  $T_k$

# PLSA: Assumptions

- **Bag-of-words:** treat docs as *memoryless* source, words are generated independently

$$sim(Q, D) = P(Q|D) = \prod_w P(w|D)^{C(w,Q)}$$

- **Conditional independent:** the doc  $D$  and word  $w$  are independent conditioned on the state of the associated latent variable  $T_k$

$$P(w, D|T_k) \approx P(w|T_k)P(D|T_k)$$

$$\begin{aligned}
 P(w|D) &= \sum_{k=1}^K P(w, T_k|D) = \sum_{k=1}^K \frac{P(w, D, T_k)}{P(D)} = \sum_{k=1}^K \frac{P(w, D|T_k)P(T_k)}{P(D)} \\
 &= \sum_{k=1}^K \frac{P(w|T_k)P(D|T_k)P(T_k)}{P(D)} = \sum_{k=1}^K \frac{P(w|T_k)P(T_k, D)}{P(D)} \\
 &= \sum_{k=1}^K P(w|T_k)P(T_k|D)
 \end{aligned}$$

# PLSA: Training (1/2)

- Probabilities are estimated by maximizing the collection likelihood using the Expectation-Maximization (EM) algorithm

$$\begin{aligned} L_C &= \sum_D \sum_w C(w, D) \log P(w|D) \\ &= \sum_D \sum_w C(w, D) \log \left[ \sum_{T_k} P(w|T_k) P(T_k|D) \right] \end{aligned}$$

EM tutorial:

- Jeff A. Bilmes ["A Gentle Tutorial of the EM Algorithm and its Application to Parameter Estimation for Gaussian Mixture and Hidden Markov Models,"](#) U.C. Berkeley TR-97-021

## PLSA: Training (2/2)

- E (expectation) step

$$P(T_k | w, D) = \frac{P(w | T_k) P(T_k | D)}{\sum_{T_k} P(w | T_k) P(T_k | D)}$$

- M (Maximization) step

$$\hat{P}(w | T_k) = \frac{\sum_D C(w, D) P(T_k | w, D)}{\sum_w \sum_D C(w, D) P(T_k | w, D)}$$

$$\hat{P}(T_k | D_i) = \frac{\sum_w C(w, D) P(T_k | w, D)}{\sum_{w'} C(w', D)}$$

# PLSA: Latent Probability Space (1/2)

Dimensionality  $K=128$  (latent classes)

Aspect 1	Aspect 2	Aspect 3	Aspect 4

Sketch of the probability simplex and a convex region spanned by class-conditional probabilities in the aspect model.

medical imaging    image sequence    context of contour    phonetic  
analysis    boundary detection    segmentation

$$\begin{aligned}
 P(w_j, D_i) &= \sum_{T_k} P(w_j, T_k, D_i) = \sum_{T_k} P(w_j | T_k, D_i) P(T_k, D_i) \\
 &= \sum_{T_k} P(w_j | T_k) P(T_k) P(D_i | T_k) \\
 \mathbf{P}(\mathbf{W}, \mathbf{D}) &= \hat{\mathbf{U}} : (P(w_j | T_k))_{j,k} \cdot \hat{\mathbf{\Sigma}} : \text{diag}(P(T_k))_k \cdot \hat{\mathbf{V}} : (P(D_i | T_k))_{i,k}
 \end{aligned}$$

# PLSA: Latent Probability Space (2/2)

$$P(w_j, D_i) = \sum_{T_k} P(w_j | T_k) P(T_k) P(D_i | T_k)$$

# PLSA: One more example on TDT1 dataset

aviation	space missions	family love	Hollywood love
Aspect 1	Aspect 2	Aspect 3	Aspect 4
plane	space	home	film
airport	shuttle	family	movie
crash	mission	like	music
flight	astronauts	love	new
safety	launch	kids	best
aircraft	station	mother	hollywood
air	crew	life	love
passenger	nasa	happy	actor
board	satellite	friends	entertainment
airline	earth	cnn	star

The 2 aspects to most likely generate the word ‘flight’ (left) and ‘love’ (right), derived from a  $K = 128$  aspect model of the TDT1 document collection. The displayed terms are the most probable words in the class-conditional distribution  $P(w_j | z_k)$ , from top to bottom in descending order.

# PLSA: Experiment Results (1/4)

- Experimental Results

- Two ways to smoothen empirical distribution with PLSA

- Combine the cosine score with that of the vector space model (so does LSA)

**PLSA-U\*** (See next slide)

- Combine the multinomials individually

**PLSA-Q\***

$$P_{PLSA}(w|D) = \sum_{k=1}^K P(w|T_k)P(T_k|D)$$

$$P_{PLSA-Q^*}(w|D) = \lambda \cdot P_{Empirical}(w|D) + (1-\lambda) \cdot P_{PLSA}(w|D)$$

$$P_{Empirical}(w|D) = \frac{c(w,D)}{c(D)}$$

$$P_{PLSA-Q^*}(Q|D) = \prod_{w \in Q} \left( \lambda \cdot P_{Empirical}(w|D) + (1-\lambda) \cdot P_{PLSA}(w|D) \right)^{c(w,D)}$$

Both provide almost identical performance

- It's not known if PLSA was used alone

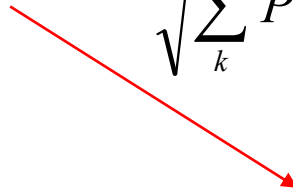

# PLSA: Experiment Results (2/4)

## PLSA-U\*

- Use the low-dimensional representation  $P(T_k | Q)$  and  $P(T_k | D)$  (be viewed in a  $k$ -dimensional latent space) to evaluate relevance by means of cosine measure
- Combine the cosine score with that of the vector space model
- Use the ad hoc approach to re-weight the different model components (dimensions) by

$$R_{PLSA-U^*}(Q, D) = \frac{\sum_k P(T_k | Q)P(T_k | D)}{\sqrt{\sum_k P(T_k | Q)^2} \sqrt{\sum_k P(T_k | D)^2}} \quad , \text{ where } P(T_k | Q) = \frac{\sum_{w \in Q} C(w, Q) P(T_k | w, Q)}{\sum_{w' \in Q} C(w', Q)}$$

online folded-in

$$\tilde{R}_{PLSA-U^*}(Q, D) = \lambda \cdot R_{PLSA-U^*}(Q, D) + (1 - \lambda) \cdot R_{VSM}(\vec{Q}, \vec{D})$$

# PLSA: Experiment Results (3/4)

• **Why**  $R_{PLSI-Q^*}(Q, D_i) = \frac{\sum_k P(T_k|Q)P(T_k|D_i)}{\sqrt{\sum_k P(T_k|Q)^2} \sqrt{\sum_k P(T_k|D_i)^2}}$  ?

- Reminder that in LSA, the relations between any two docs can be formulated as

$$A^T A = (U^T \Sigma^T V^T)^T (U \Sigma V^T) = V \Sigma^T U^T U \Sigma V^T = (V \Sigma^T) (V \Sigma^T)^T$$

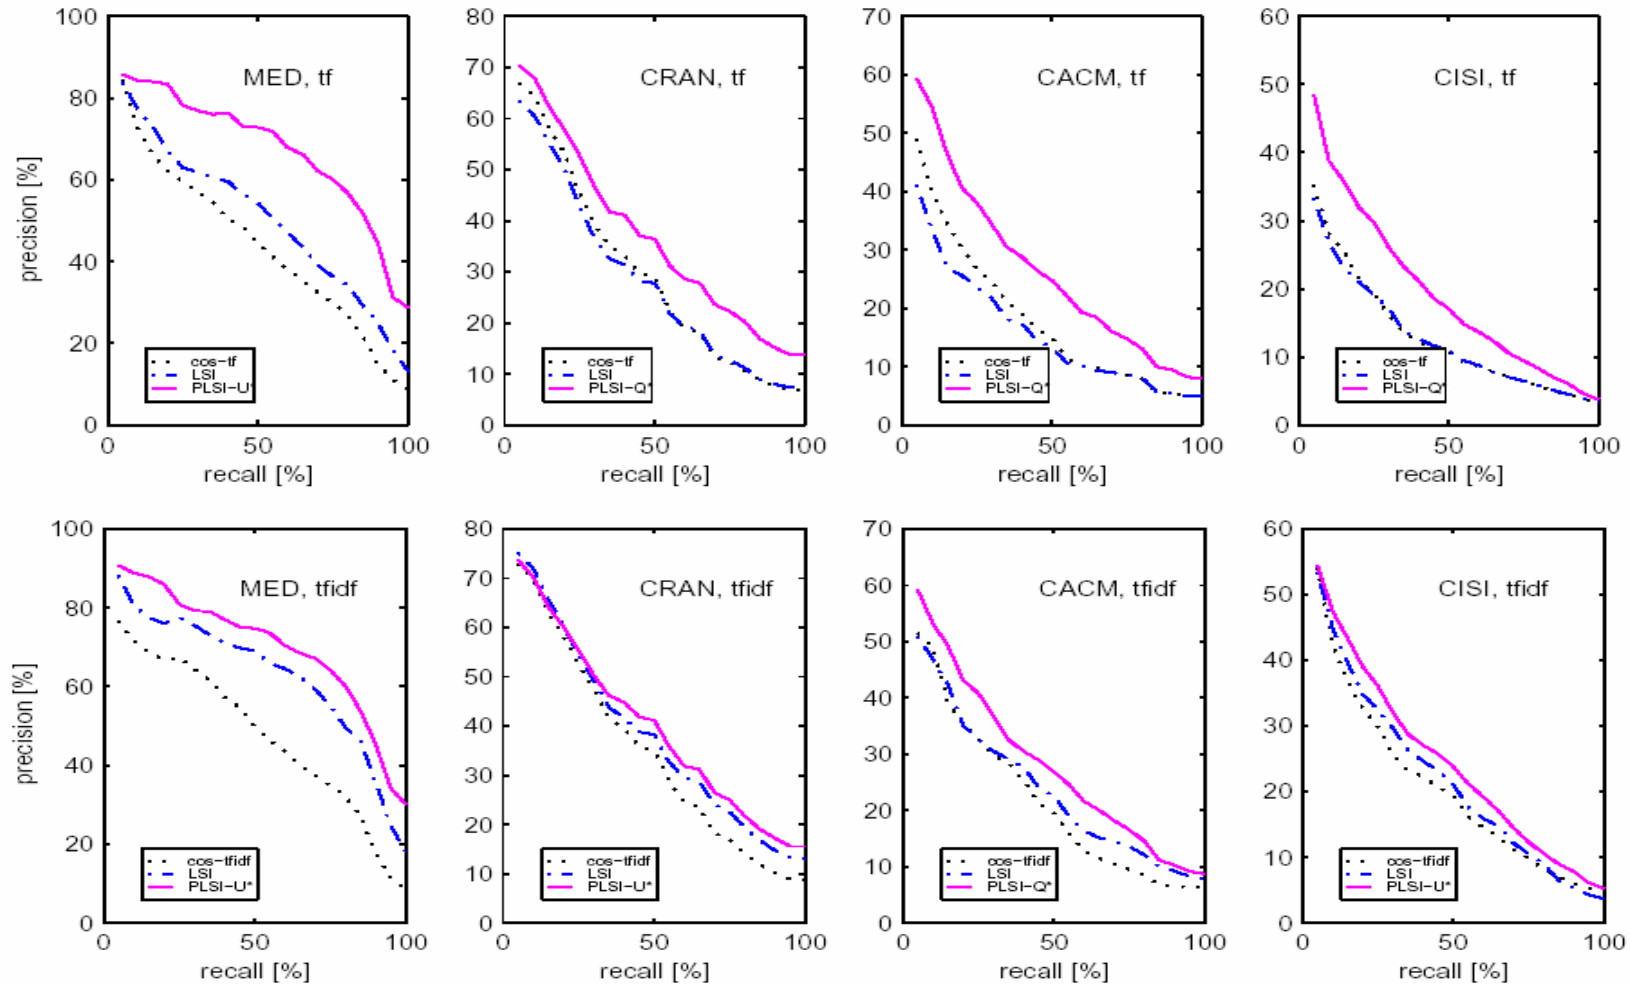

$$sim(D_i, D_s) = coine(\hat{D}_i \Sigma, \hat{D}_s \Sigma) = \frac{\hat{D}_i \Sigma^2 \hat{D}_s^T}{|\hat{D}_i \Sigma| |\hat{D}_s \Sigma|}$$

- **PLSA mimics LSA in similarity measure**  $\hat{D}_i$  and  $\hat{D}_s$  are row vectors

$$\begin{aligned}
 R_{PLSI-Q^*}(D_i, D_s) &= \frac{\sum_k P(D_i|T_k)P(T_k)P(T_k)P(D_s|T_k)}{\sqrt{\sum_k [P(D_i|T_k)P(T_k)]^2} \sqrt{\sum_k [P(D_s|T_k)P(T_k)]^2}} \\
 &= \frac{\sum_k P(T_k|D_i)P(D_i)P(T_k|D_s)P(D_s)}{\sqrt{\sum_k [P(T_k|D_i)P(D_i)]^2} \sqrt{\sum_k [P(T_k|D_s)P(D_s)]^2}} \\
 &= \frac{\sum_k P(T_k|D_i)P(T_k|D_s)}{\sqrt{\sum_k P(T_k|D_i)^2} \sqrt{\sum_k P(T_k|D_s)^2}}
 \end{aligned}$$

$P(D_i|T_k)P(T_k) = P(T_k|D_i)P(D_i)$

# PLSA: Experiment Results (4/4)

# PLSA vs. LSA

- Decomposition/Approximation
  - **LSA**: **least-squares criterion** measured on the L2- or Frobenius norms of the word-doc matrices
  - **PLSA**: **maximization of the likelihoods functions** based on the cross entropy or Kullback-Leibler divergence between the empirical distribution and the model
- Computational complexity
  - LSA: SVD decomposition
  - PLSA: EM training, is time-consuming for iterations ?
